zhongqianwen77@gmail.com

Abstract: Electric Vehicles (EVs) is found to be a capable method to enhance the transport systems. Nevertheless, higher supply of EVs leads to higher demand of electricity. An effectual technique to decrease this impact is to combine renewable energy sources (RESs) with charging infrastructure. This research aims to set up a dispatch policy using optimization theory for enhancing the economy of microgrid (MG) systems. The most significant intention is to lessen the functional cost of system while meeting system load requirements. Accordingly, the output constraints related to distributed power supply are optimized using Grasshopper Optimization with Genetic Algorithm (GOAGA). Further, the superiority of GOAGA is authenticated over existing works regarding wide-ranging measures. From the examination, the GOAGA model reveals a minimum cost value for C_1 , C_2 and total cost over other techniques, therefore ensuring the superior economy of MG.

Keywords: Microgrid; Renewable energy; Electric vehicles; Photo Voltaic; GOAGA model.

Nomenclature

Abbreviation	Description
GOAGA	Grasshopper Optimization with Genetic Algorithm
DE	Diesel Engine
DG	Distributed Generation
EVs	Electric vehicles
EES	Electric Energy Storage
GHG	Global Greenhouse Gas
HVAC	Heating, Ventilation and Air-Conditioning Systems
MG	Microgrid
MKEM	Micro-grid Key Elements Model
PV	Photo Voltaic
RD	Regulation Down
RU	Regulation Up
RES	Renewable Energy Sources
WT	Wind Turbine

1. Introduction

Nowadays, the transport is liable for 14% of GHG emissions [34]. The construction sector generates huge quantity of greenhouse gas emissions and is accountable for just about 35% of energy utilization owing to electric devices [3]. For energy domain, it is intended to reduce the energy and biological impact using proper strategies, depending on RES. Consequently, the implementation of HVAC systems were examined gradually in the earlier decades [9,10]. Moreover, the private transport is said to be the most important cause for contaminant, such as SO_x , NO_x , CO_2 , CO and particulate matters [11-13]. As this causes ecological issue, the diffusion of electricity is advantageous chiefly for crowded urban areas [14] [15].

Consequently, to diminish the ecological cost of the sector, the exploitation of EVs has turned out to be a practicable option [16,17]. In past decades, EVs have turn out to be widespread, mainly due to its lesser flue gas emissions and minor reliance on oil. Alternatively, a significant crisis associated with EVs is that, it's superior penetration increase transformer congestion and leads to heavier power demand to

the grid. A capable approach to develop the effect is to amalgamate local power generation like RESs into EV charging infrastructure [18,19].

Moreover, the incorporation of RESs to power EVs can assist in decreasing the pollutions, with a substantial decarbonisation effect and therefore, the effectiveness of resources could be developed [27] [28] [29]. Although EVs make zero direct emissions in urban areas, they are charged from the power grid that mostly depends on fuel-fossil power plants [20-23]. However, there is a deficient in precise analysis that takes account of interaction and integration of EVs with RESs [24,30,31].

The arrangement of the paper is specified as: Section 2 portrays the review. Section 3 explains the problem formulation and section 4 portrays the optimal tuning of power limit constraints via GOAGA algorithm. Section 5 illustrates the outcomes and the paper is concluded by section 6.

2. Literature Review

2.1 Related Works

In 2019, Jain *et al.* [1] have offered a model that determined the 2-way energy storage potential of several EVs for contributing RD and RU to grid. The offered method employed a design that scheduled the power from grid by treating the mobility based electric constraints. Accordingly, 2 functioning places such as, residence and workplace were taken for stipulating the supplementary services. In addition, the performance of the modelled scheme was examined efficiently in terms of energy exploitation and cost.

In 2020, Shi *et al.* [2] have modelled an effective approach that enhanced the economy and security of MG systems. The uncertainties of EVs wind power and SOC were formulated as “uncertainty prediction sets”. Furthermore, the adopted model has enhanced the absorption ratio of RES when regulating the discharging and charging of EVs. Thereby, minimum implementation costs were attained under varied constraints. The experimentation revealed that the offered technique considerably improved the capability and robustness over the existing schemes.

In 2020, Hariri *et al.* [3] have designed a new generalized systematic method for reliability evaluation in smart grid. As a most important contribution, a state matrix was developed that observed the operation modes of smart grid by employing the graph theory. In addition, a novel wide-ranging model of PHEVs was developed that calculated the entire uncertainties of the system. Moreover, the performance of the developed technique was efficiently analyzed regarding sensitivity and precision.

In 2019, Buonomano *et al.* [4] have analysed the financial, environmental and energy performances of forthcoming state, in which EVs were related with efficient buildings equipped with EES. The financial system was dynamically simulated within the “TRNSYS environment”, wherein most important consideration was offered to the appropriate system control policies that intended at optimizing solar power for electricity purpose. At last, the development of the offered model was verified in terms of sensitivity analysis.

In 2019, Imane *et al.* [5] have modelled a smart grid design that incorporated several embed main grid and MG. In addition, unique focus was offered to MG systems by employing a MKEM. The virtualization of developed grid model dealt with the issues associated with back-feeding, PV diffusion and supply irregularities. The simulated results revealed the impact of RES integration and it emphasized the function of batteries that sustained the system consistency.

3. Problem Formulation

3.1 Objective Function

The intention of this work is to diminish the net emission and operation cost in a simultaneous way. The arithmetical modelling is described in this section.

The objective function (obj) of modelled scheme is exposed in Eq. (1), in which W_1 and W_2 indicate the 2 weighting coefficients that are presented to examine the impact of diverse values on the schedule system.

$$\text{obj} = \text{Min}_{P_{i,t}^{\text{PEV}_{n,t}}} \{W_1 C_1 + W_2 C_2\} \quad (1)$$

The objective function C_1 and C_2 are defined as exposed in Eq. (2) and Eq. (3), in which C_1 points out the operation cost of the system (along with the maintenance cost, operation and fuel) and C_2 refers to the environmental treatment cost (that consist of NO_x , SO_2 , and CO_2).

$$C_1 = \sum_{t=1}^T \left\{ \sum_{i=1}^M [O_f(P_{i,t}) + O_{OM}(P_{i,t}) + O_{BAT}(PEV_t)] + O_{grid,t} \right\} \quad (2)$$

$$C_2 = \sum_{i=1}^M \sum_{g=1}^G (O_g v_{i,g}) P_i + \sum_{g=1}^G (O_g v_{grid,g}) P_{grid} \quad (3)$$

In Eq. (3), $v_{i,g}$ refers to the discharge coefficient pollutant of i type DGs; $v_{grid,g}$ refers to coefficients of discharge pollutants of main power grid; O_g refers to treatment cost of g^{th} contaminant emission; P_i refers to output power of i^{th} power supply; P_{grid} refers to grid power. In Eq. (2), PEV_t signifies the whole discharging and charging power of EVs at time t , and $P_{i,t}$ signifies the kind of distributed power supply that satisfied $P_{i,t} = [PDE_{h,t}; PWT_{1,t}]$, $t = 1, 2, \dots, 24$. In addition, $PDE_{h,t}$ signifies the h^{th} DE output at time t , $PWT_{1,t}$ signifies the 1^{th} WT output at time t . The whole operation cost of the MG system in \$(USA) take account of the fuel costs of DGs $O_f(\bullet)$, the operational and maintenance cost $O_{OM}(\bullet)$, the degradation cost of battery $O_{BAT}(\bullet)$, and the transmission cost amid main power grid and the MG. The cost functions of objective function C_1 are elucidated in Eq. (4) - Eq. (7).

$$O_f(\bullet) = \{C_1 PDE_t^2 + C_2 PDE_t + C_3\}_{DE} \quad (4)$$

$$O_{OM}(\bullet) = K_{OM} P_{i,t} \quad (5)$$

$$O_{grid,t} = \begin{cases} P_{grid,t}^+ N_{sell,t} & P_d > P_i \\ P_{grid,t}^- N_{buy,t} & P_d < P_i \end{cases} \quad (6)$$

$$O_{BAT}(\bullet) = A_n PEV_t^2 + B_n C_2 PEV_t + C_n \quad (7)$$

In Eq. (4), C_1 ; C_2 ; C_3 refers to the cost factors of DE; A_n ; B_n ; C_n stands for the constraints of battery degradation cost; the $N_{buy,t}$ and $N_{sell,t}$ stands for the coefficients of transmission amongst main power grid to MG at time t ; $P_{grid,t}^+$ and $P_{grid,t}^-$ stands for the transmission power of main power grid and MG in that order and K_{OM} stands for the OM cost factor. In Eq. (6), P_d point out the demand power.

3.2 Constraints

The output parameters linked with the distributed power supply is mainly addressed in the form of power limits, which consist of the output parameters of WT, output constraint of conventional power supplies in real-time, discharging - charging power constraints of EVs and power limit of grids:

$$P_{i,t}^{min} \leq P_{i,t} \leq P_{i,t}^{max} \quad (8)$$

$$0 \leq PWT_t \leq PWT_t^H \quad (9)$$

$$P_{buy}^{min} \leq P_{grid,t}^+ \leq P_{buy}^{max} \quad (10)$$

$$P_{sell}^{min} \leq P_{grid,t}^- \leq P_{sell}^{max} \quad (11)$$

$$0 \leq PEV_{d,t} \leq PEV_{d,t}^{max} \quad (12)$$

$$0 \leq PEV_{c,t} \leq PEV_{c,t}^{max} \quad (13)$$

Eq. (8) signifies the output constraint of DE in real-time, Eq. (9) refers to the output constraint of WT, and Eq. (10) and Eq. (11) refers to the grid power constraints of main grid and the grid power constraints of MG. Eq. (13) and Eq. (12) point out the discharging and charging power constraints of EVs in that order.

4. Optimal Tuning of Power Limit Constraints Via GOAGA Algorithm

4.1 Solution Encoding

The presented scheme intends to accomplish 5 optimal factors namely, (i) optimal allotment of WT and DE (ii) optimal achievement of PDE (iii) optimal achievement of PWT (iv) optimal $P_{grid,t}^+$ and (v) optimal $P_{grid,t}^-$. The input solution offered to the GOAGA algorithm is exposed in Fig. 1. The optimal allotment of WT and DE is regarded for 24×5 (24 point out the hours and 5 point out the count of DG); i.e. for each hour, 5 DGs will be subjugated and its bound lies amongst 0 and 1. The DG with maximal

value is allotted with the WT, whereas, the residual 4 DGs are allotted with DE. Moreover, the PDE value lies amongst 1500kW and 500kW and it is considered for 24×4 (for every hour, 4 DGs will be exploited). The value of PWT lie amongst 500e3 and 500e2 and it is considered for 24×1 (for every hour, 1 DG is deployed). In addition, the optimal value of $P_{grid,t}^+$ lie amongst 0kW and 300kW and the optimal value of $P_{grid,t}^-$ lie amongst 0kW and 150kW and is measured for 24 hours.

Fig. 1. Solution encoding

4.2 GOAGA Algorithm

GA is a heuristic optimization scheme that is usually deployed for enhance the solutions and for resolving the multi-objective issues. However, the convergence speed of GA is inferior. Moreover, the GOA model is an optimization technique depending on the activities of grasshopper swarms in nature. The convergence speed of GOA is superior and simultaneously the accurateness of detecting the solutions is high. Thereby, the GA and GOA are merged to form the GOAGA technique. Hybrid techniques are found to be capable for resolving complex optimization issues. The steps in the GOAGA model [16] are portrayed below:

Step 1: Initiate Pop_i (the random population), current iteration t , maximal value cmx , minimal value cmn and maximal iteration count L .

Step 2: Evaluate the search agent fitness

Step 3: The best search agent is regarded as T

Step 4: While ($t < L$) move to following steps

Step 5: Constraint c is updated as in Eq. (14)

$$c = cmx - t \frac{cmx - cmn}{L} \quad (14)$$

Step 6: For (every search agent), the distance among the grasshoppers is stabilized in [1,4] interval.

Step 7: The position of present search agent is updated as per Eq. (15).

$$Pos_i^a = c \left(\sum_{j=1}^M c \frac{Upper_s - Lower_s}{2} r (J_j^a - J_i^a) \frac{J_j - J_i}{a_{ij}} \right) + \hat{T}_a \quad (15)$$

Accordingly, a_{ij} refers to the distance among i^{th} and the j^{th} grasshopper and it is described as $a_{ij} = |J_j - J_i|$. Moreover, r strength of social forces and M refers to count of grasshoppers.

Step 7: Calculate fitness by means of Eq. (1)

Step 8: Depending on minimal fitness, the best 2 solutions are found.

Step 9: Update the position of search agent by means of the cross-over of GA and again. Evaluate fitness by means of Eq. (1). The finest two solutions obtained from GA and GOA is united. Again calculate fitness and carry the search agent to its original location.

Step 10: Terminate

5. Results and Discussions

5.1 Simulation Procedure

The developed GOAGA approach for improving the economy of MG system was executed in MATLAB and the related outcomes were noticed. As per the developed model, the cost analysis was performed regarding time (hour) by distinguishing it with other existing schemes like WOA [14], DA [15], CSA [12] and GWO [13]. In addition, stochastic analysis as well as robust analysis was performed in terms of power in kilowatt (kW). Table I exposes the environmental constraints that demonstrates the pollution and cost emission (kW).

Table 1. Environmental constraints

Type	Treatment cost(\$/kg)	Coefficient to Pollutant emission (g/kW)		
		Main grid	WT	DE
NO _x	1.1765	1.6	0	10.09
CO ₂	0.0309	889	0	680
SO ₂	0.8824	1.8	0	0.306

5.2 Stochastic Optimization Analysis

The analysis for GOAGA model in terms of stochastic optimization is exposed in Table II. As per the resultants in Table II, EVs discharged throughout peak hours assists DE to meet-up the load demand that lessen the high economical cost efficiently. Meanwhile, during 23.00 to 1.00, the load demand decreases while the WT output rise. At this instance, EVs are recharged to gratify the travel requirements of users for the following day that improve the utilization rate of WT power.

Table 2. Examination on stochastic optimization

Time (hr)	Power in kW			
	DE	WT	P _{grid+}	P _{grid-}
16	100	900	500	0
17	500	350	500	0
18	250	450	500	0
19	100	900	500	0
20	100	1000	500	0
21	100	600	500	0
22	100	600	500	0
23	0	700	450	0
1	0	1000	200	0
0	0	1000	300	0
2	150	500	500	0
3	400	700	500	0

5.3 Analysis on Robustness

The assessment for the GOAGA model regarding robustness is exposed in Table III. On evaluating the stochastic analysis with robust analysis, the resultants of robust analysis is found to meet more charging demands of EVs' when there is lesser EVs and lesser WTs discharging loads.

Table 3. Examination on robust optimization

Time (hr)	Power in kW			
	DE	WT	P _{grid+}	P _{grid-}
16	100	1000	500	0
17	600	250	500	0
18	450	250	500	0
19	400	650	500	0
20	400	700	500	0
21	200	250	500	0
22	200	350	500	0
23	150	600	500	0
3	500	200	500	0
2	250	400	500	0
1	0	650	400	0
0	150	650	500	0

5.4 Cost Analysis

Table IV demonstrates the cost analysis of GOAGA model over compared approaches such as WOA, DA, CSA and GWO for diverse time intervals (hours). From the examination, the GOAGA model has depicted a minimal cost value for C_1 , C_2 and total cost over other techniques, therefore guarantying the enhanced economy of MG. Therefore, from the evaluation, it is clear that the GOAGA model has attained improved performance in cost assessment over the existing methods.

Table 4. Cost Analysis of developed scheme over conventional models for different hours

Hour	C_1					C_2					Total cost				
	WOA [14]	DA [15]	CSA [12]	GWO [1]	GOAG A	WOA [14]	DA [15]	CSA [12]	GWO [1]	GOAG A	WOA [14]	DA [15]	CSA [12]	GWO [1]	GOAG A

6. Conclusion

This work has developed a dispatch strategy that improved the economy of MG by means of CGWO model. Here, the primary objective was to diminish the operation cost of the system while satisfying the load necessities. Furthermore, the output parameters related with distributed power supply was subjected to optimization, for which GOAGA model was used. Accordingly, the performance of GOAGA model was evaluated over existing models with respect to grid and cost analysis. From the examination, the GOAGA model has revealed a minimum cost value for C_1 , C_2 and total cost over other techniques, therefore ensuring the superior economy of MG. Thus, from the assessment, it is obvious that the GOAGA model has attained enhanced performance in terms of cost assessment. Moreover, EVs discharged throughout peak hours assists DE to meet-up the load demand that lessen the high economical cost efficiently. Therefore, the better outcomes establishes the efficacy of the developed dispatch model.
